# Analysis of Markovian Population Models Dissertation Defense

Michael Backenköhler

Saarland Informatics Campus

September 20, 2022

#### Motivation

- Example
- ▶ list other applications: queueing, metabolic networks, switches etc.

Semantics

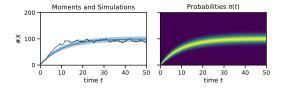

- counting agents / population size
- continuous time
- exponential jump times / CTMC dynamics
- example: birth-death process

Stationary Distribution - Foster-Lyapunov Functions

- ergodic chains converge to unique distribution
- how does this distribution look like for infinite state-spaces?
- use Foster-Lyapunov function to bound sets
- locally augment functions for tighter sets / bounds

#### Moment Dynamics

- alternative approach: look at moments instead of states
- ightharpoonup expected values, e.g. E(X),  $E(X^2)$

Moment formula

$$\frac{d}{dt}E\left(f(X_t)\right) = \sum_{j=1}^{n_R} E\left(\left(f(X_t + v_j) - f(X_t)\right)\alpha_j(X_t)\right)$$

ODE system not closed

#### Martingale Process

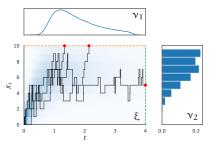

analytic integration and resulting martingale process

$$Z_T := w(T)f(X_T) - w(0)f(X_0) - \int_0^T \frac{dw(t)}{dt}f(X_t) dt$$
$$-\sum_{j=1}^{n_R} \int_0^T w(t)(f(X_t + v_j) - f(X_t))\alpha_j(X_t) dt$$

- ▶ time-weighting:  $w(t) = t^k$ ,  $k \in \mathbb{N}$  or  $w(t) = \exp(\lambda t)$
- ▶ known expectation:  $E(Z_T) = 0$ ,  $\forall T \ge 0$

Martingale Process and Linear Moment Constraints

 expected occupation time and exit measures (in relation to expectation of the martingale)

▶  $0 = E(Z_T)$  is a linear moment constraint constraint on  $v_1$ ,  $v_2$ , and  $\xi(w(t) = t^k)$  (TODO: integrate moms and figure)

Moment Matrices and Semi-Definite Programs

- semi-definite moment constraints (positive variance as example)
- hint at localizing matrices

Results and Practical Issues

- moment stiffness, re-scaling issue
- some examples

Hausdorff Constraints and Linear Programs

- linear constraints possible if domains (time and space) are finite
- ▶ 1D visualization of Hausdorff constraints

Using Correlated RVs with Known Expected Value

- segue: use the same martingale constraints to enhance MC estimation
- use correlations between target RV and martingales (linear regression, i.e. control variates)

#### Finding Efficient Sets of Control Variates

- time-weighting has a large influence on the correlation
- Infinitely many possibilities (cost needs to be controlled though)
- variates can be highly redundant (correlated) and incur an additional cost
- Alg. 1: Tighten an initial proposal set
- Alg. 2: Re-sample promising candidates

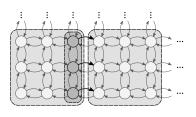

Selection Algorithms

Results

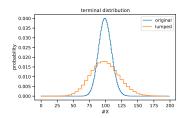

▶ best example?

### State-Space Aggregation

Treating Hyper-Cubes of States as One (Backenköhler et al. 2021a,b)

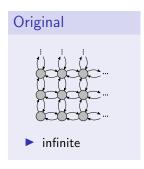

- ▶ hyper-cube macro-states
- assumption: uniform dist. within
- closed-form transition rates

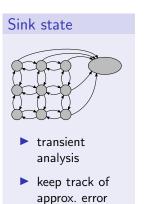

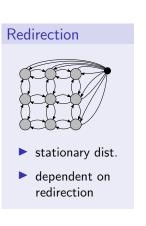

- resulting distribution more "flat"
- locate main probability mass

### Stationary Distribution

#### Finite-Space Projection

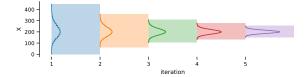

### Stationary Distribution

#### Iterative Refinement Algorithm

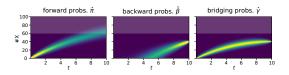

A simple refinement based on approximate solutions:

- 1. start with macro-states of size  $2^k$
- 2. compute approximate distribution
- 3. remove states with low probability
- 4. split the remaining states
- 5. go to step 2

#### Bridging Problem

#### Dynamical Analysis Under Initial and Terminal Constraints

#### Forward Probabilities

How the process evolves with time:  $Pr(X_t = x \mid X_0 = 0)$ 

#### **Backward Probabilities**

Probability of ending up in a given state:  $Pr(X_T = 40 \mid X_t = x)$ 

#### **Bridging Probabilities**

In between:  $Pr(X_t = x \mid X_0 = 0, X_T = 40)$ 

### **Bridging Problem**

Refinement

### Importance Sampling

### Conclusions and Future Directions
